How this works: find your card below, then write your parts in the WORKING DOC: https://docs.google.com/document/d/1owqNOi9vrhBqCWEA_AhqBJI2JwBY1opYjd3HzqUVn5s/edit. Press Ctrl+F there and type your name to find your parts (yellow lines).

Team 05 · P2 Plan

Due Sun Nov 8, 11:59 PM. Everything the professor gave us is on Canvas → Files: the P2 template (the empty document we fill in) and the lecture slides each card mentions.

The big picture

In P1 we said **what** our website does: Whoosh Events collects UTD Calendar and Nebula club events into one list students can filter. In P2 we explain **how we would build it**, in this order:

1. **How a student uses it**, step by step (Ahmed).
2. **What "things" the system keeps track of**, like events and tags (Ahmed).
3. **What big pieces the system is made of and where they run** (Habib picks the overall shape, Austin draws it).
4. **A quick test** that we can really get the events from both sites (Jaiom).
5. **Checking that everything connects** and nothing is missing (Atharva, Sinan).

Who does what

Person	In short	Time	Due	Checks the work of
Ahmed	Fix P1 + how a student uses the site + what the system keeps track of	9–10 h	Fri Nov 6, 11:59 PM	Atharva
Habib	Pick the overall shape of the system and its speed/reliability goals	2–3 h	Fri Nov 6, 11:59 PM	Austin
Jaiom	Quick test that we can get the events + risks and open questions	2–3 h	Fri Nov 6, 11:59 PM	Sinan

Austin	Set up GitHub, draw the system's pieces, submit at the end	2–3 h	GitHub at the meeting; rest Fri Nov 6, 11:59 PM	Habib
Atharva	Check that every requirement connects through to the design	2–3 h	Sat Nov 7, 6 PM	Ahmed
Sinan	Short summary tables + team plan and sign-offs	1.5–2 h	Sat Nov 7, 6 PM	Jaiom

How you get your own points (12 of the 60 are per person)

The professor grades each person only from what they put on our GitHub page (github.com/AO2-Git/CS3354-Team05-Project). In P1 nobody did this, so everyone lost half these points. Three steps:

1. **Upload your part** to GitHub from your own account, as a "pull request" (a request to add your file that a teammate approves). We'll do the first one together at the meeting.
2. **Check one teammate's upload** and leave one real comment (the "Checks the work of" column above).
3. **Write one row about yourself** in section 0.1 of the working doc: what you did, with the links to your uploads.

Using AI is allowed. Just tell Sinan which tool you used and for what.

Meeting: Wed Nov 4, 4:00–5:30

1. **4:00–4:20** Austin sets up GitHub; everyone joins, uploads one small file together, and writes their GitHub username on the working doc's first page.
2. **4:20–4:45** Ahmed walks through how a student uses the site, and the "things" it keeps track of.
3. **4:45–5:10** Habib leads: we pick the system's overall shape and sketch its pieces on a whiteboard. Austin takes a photo.
4. **5:10–5:25** Jaiom explains the quick test; we agree what to measure.
5. **5:25–5:30** Confirm deadlines and who checks whose work.

Ahmed · your part

Our project: Whoosh Events, one website listing UTD Calendar and Nebula club events with filters.

In short: fix what lost points in P1, then describe how a student uses the site and what "things" the system keeps track of.

Due: Fri Nov 6, 11:59 PM. **Time:** 9–10 h. **Read first:** Lessons 13–14 slides on Canvas (about 1 h).

Part	What to do
0.2	A list of what we fixed since P1, one row per thing the professor complained about. Already drafted; just check it at the end.
1–3	Our P1 text is already pasted in. Make 3 requirement tests clearer (FR-02, FR-04, QR-02), and replace the old table in 3.5 with one line: "See section 9.1."
2.2	Ask 5+ students "how do you find campus events now?" and put their answers in a small table. This proves students actually need our site.
4	Write 3 "use cases": short scripts of a student using the site. Each row is one back-and-forth: what the student does, then what the site shows. Add what happens when something goes wrong. The 3 are: find events by tag, view an event's details, and add an event to my calendar.
5.1	A simple diagram of the "things" the site keeps track of (Event, Tag, Source Site, Organizer), what each one has (title, date…), and how they relate ("one event has many tags").
5.2	For 2 of the use cases: a table of who talks to whom at each step, then the same thing as a diagram with one arrow per row.

Your own points: upload your part to GitHub from your account, check Atharva's upload with one comment, and write your row in section 0.1.

Habib · your part

Our project: Whoosh Events, one website listing UTD Calendar and Nebula club events with filters.

In short: decide the overall shape of the system, and write down how fast and reliable it has to be. Everyone else builds on your choice.

Due: Fri Nov 6, 11:59 PM. **Time:** 2–3 h. **Read first:** Lessons 15–16 slides on Canvas, "High-Level Design" (about 45 min).

Part	What to do
6.1	3 short goals, each with a number, written as "when this happens → the site does this → within this much time". Use the ones we already have from P1: the page loads in 3 seconds (QR-01), a new event shows up within 2 hours (QR-03), and if a source site is down we still show its last events (QR-06).
6.2	Pick the system's overall shape from the list in Lesson 15 (for example "a website plus a background job that collects events every hour"). Name 2 other shapes we didn't pick, and say in a few lines why ours fits the 3 goals above better.
ADR-01	A "decision record": a short fill-in form in the template (section 7.1) that writes down the choice from 6.2: what we chose, what else we considered, and what we give up by choosing it.

At the meeting: lead the shape choice with everyone so Austin can draw it.

Your own points: upload your part to GitHub from your account, check Austin's upload with one comment, and write your row in section 0.1.

Jaiom · your part

Our project: Whoosh Events, one website listing UTD Calendar and Nebula club events with filters.

In short: run a quick test that we can really get the events from both sites, and update the risks and questions from P1.

Due: Fri Nov 6, 11:59 PM (do the test first; the rest uses its numbers). **Time:** 2–3 h.

Part	What to do
8	The professor calls this a "spike": a tiny test program, not real product code. About 30–40 lines of Python is enough: • UTD Calendar has a ready-made data link that returns events directly: calendar.utdallas.edu/api/2/events • The Nebula clubs page already lists the events in its page: clubs.utdnebula.com/events Fetch both and write down: how many events you got, how many have title, date, time and location, and how many seconds it took. Upload the code, a short README and the numbers to GitHub in the folder /spikes/S-01. Then fill the small form in section 8 of the working doc.
ADR-02	A "decision record" (a short fill-in form in template section 7.1): how often we collect events (for example every hour and save a copy) and whether we use UTD's data link or read its web pages. Use your numbers as the reason.
10.3	The risk table from P1: fill in the empty R5, say whether R1–R4 got better or worse, and add 1 new risk (for example "a site changes its layout"). Each fix gets a person's name.
11	The questions from P1 (Q1–Q3): write the answers your test found.

At the meeting: explain the test; we agree on what to measure.

Your own points: upload your part to GitHub from your account, check Sinan's upload with one comment, and write your row in section 0.1.

Austin · your part

Our project: Whoosh Events, one website listing UTD Calendar and Nebula club events with filters.

In short: set up our GitHub, draw the system's pieces and where they run, and submit the final PDF.

Due: GitHub at the Wed meeting (everyone needs it); the rest by Fri Nov 6, 11:59 PM; submit Sun Nov 8 by 9 PM. **Time:** 2–3 h. **Read first:** Lessons 15–16 slides on Canvas (about 30 min).

Part	What to do
GitHub	In our repo (CS3354-Team05-Project) create 3 folders: docs/p2/sections, docs/p2/diagrams, spikes. Add the other 5 of us as collaborators.
6.3	A box diagram of the system's 4–5 main pieces (for example: event collector, event storage, website, calendar download) plus the 2 outside sites, with a small table saying what each piece does. Use the whiteboard photo from the meeting.
6.4	A second diagram of where each piece runs (the student's browser, our free host, UTD's servers), with "HTTPS" written on each connecting line, and a dashed line separating machines we control from ones we don't.
ADR-03	A "decision record" (a short fill-in form in template section 7.1): which free hosting site we use, which 2 others we looked at, and what we give up.
10.4	One paragraph: the GitHub link, the folders, and our rule that every upload gets checked by a teammate.
Submit	Sunday: delete the professor's instruction boxes, export the PDF, upload it to GitHub in docs/p2 and to Canvas. Only you submit.

Your own points: upload your part to GitHub from your account, check Habib's upload with one comment, and write your row in section 0.1.

Atharva · your part

Our project: Whoosh Events, one website listing UTD Calendar and Nebula club events with filters.

In short: check that all our sections connect to each other, which is where we lost P1 points.

Due: Sat Nov 7, 6 PM (you start once the others are done on Friday). **Time:** 2–3 h. **Read first:** the checklist at the end of the Lesson 14 slides (about 30 min).

Part	What to do
9.1	Take the requirements table you made in P1 and add columns. For each requirement, write which use case it belongs to (UC-01, UC-03, UC-02), which "thing" from Ahmed's diagram (Event, Tag…), which piece from Austin's diagram (website, event collector…), and which decision record (ADR-01, 02 or 03).
9.2	A small table of anything that doesn't connect (a requirement with no piece, a piece no requirement needs), and what we did about it.
5.3	6 yes/no checks already written in the template, for example "is every word in the use cases also in Ahmed's diagram?" For each one, write yes, or what was wrong and where we fixed it. Finding and fixing a problem counts more than all yeses.

Your own points: upload your part to GitHub from your account, check Ahmed's upload with one comment, and write your row in section 0.1.

Sinan · your part

Our project: Whoosh Events, one website listing UTD Calendar and Nebula club events with filters.
In short: short summary tables that tie the design together, plus the team plan and sign-offs.
Due: Sat Nov 7, 6 PM (you start once the others are done on Friday). **Time:** 1.5–2 h. **Read first:** skim Lessons 15–16 slides on Canvas (about 20 min).

Part	What to do
6.5	A 2-column table: each "thing" from Ahmed's diagram (Event, Tag, Source Site…) and which piece of Austin's diagram (website, event collector, storage…) handles it.
6.6	6 rows, one per design idea listed in the template (like "keep it simple" and "keep pieces separate"). For each, point to one place in our design that shows it.
7.2	A 3-row summary of our 3 decision records (Habib's, Jaiom's, Austin's): what each choice gained and what it gave up.
10.1 / 10.2	Each person's job in words (not section numbers), and a plan for P3 (due Dec 9) where every row has one name and a date.
10.5 / 12	Collect who used AI and for what into the table, and get all 6 of us to sign the last page.

Your own points: upload your part to GitHub from your account, check Jaiom's upload with one comment, and write your row in section 0.1.
